First attempts to isolate plant genes were for those genes that are abundantly expressed in a particular plant organ at a specific stage of development. However, many important gene products

These genes must, however, be regulated in a spatial and temporal manner in order to have desired effects on plant development and productivity. The habitat of plants necessitate adaptive responses with respect to the environmental changes. Starting from germination of the seed, the plant begins to sense environmental cues such as moisture, light, temperature and the presence of pathogens. [Regulatory Sequences Control Gene Expression - NDSU](#)

Spatial regulation - a type of regulation of gene expression in which a gene is only expressed in a specific location in the plant; for example, seed storage proteins. Although we can distinguish between these two types of regulation, many genes will actually fall into both classes.

In addition to spatial regulation, the growth plate also undergoes important temporal regulation. Over time, proliferation slows in the growth plate [ 6 ], causing the rate of longitudinal bone growth to decrease and approach zero as the organism approaches its adult size.

Our previous study showed that the temporal and spatial expression patterns of DL and its orthologs are highly similar to each other in rice, maize, wheat and sorghum, suggesting that a common genetic mechanism may underlie the regulation of the expression of these genes (Ishikawa et al., 2009).
